ExceptionHandling

2018.07.10.

담당교수 이 효 섭

- Exception Handling Basics
 - Defining exception classes
 - Multiple throws and catches
 - Exception specifications
- Programming Techniques for Exception Handling
 - When to throw exceptions
 - Exception class hierarchies

- Typical approach to development:
 - Write programs assuming things go as planned
 - Get "core" working
 - Then take care of "exceptional" cases
- C++ exception-handling facilities
 - Handle "exceptional" situations
 - Mechanism "signals" unusual happening
 - Another place in code "deals" with exception

- Exceptions are anomalous or exceptional situations requiring special processing – often changing the normal flow of program execution.^[wikipedia]
 - Memory allocation error - out of memory space.
 - Divide by zero.
 - File IO error.
 - ...
- Propagating failure through function calls is cumbersome.

- Imagine: people rarely run out of milk:

```
cout << "Enter number of donuts:";
cin >> donuts;
cout << "Enter number of glasses of milk:";
cin >> milk;
dpg = donuts/static_cast<double>(milk);
cout << donuts << "donuts.\n";
    << milk << "glasses of milk.\n";
    << "You have " << dpg
    << "donuts for each glass of milk.\n";
```

- Basic code assumes never run out of milk

- Notice: If no milk \rightarrow divide by zero error!
- Program should accommodate unlikely situation of running out of milk
 - Can use simple if-else structure:

```
if (milk <= 0)
    cout << "Go buy some milk!\n";
else
    {...}
```

- Notice: no exception-handling here

Exception Handling in C++

```
bool DoSomething(string* error_message) {  
    cout << "DoSomething called." << endl;  
    // Do something...  
    if (something_is_wrong) {  
        *error_message = "something is wrong.";  
        return false;  
    }  
    // Do the rest...  
    cout << "DoSomething finished." << endl;  
    return true;  
}
```

```
int main() {  
    string error_message;  
    if (!DoSomething(&error_message)) {  
        cout << "DoSomething failed : '"  
            << error_message << "'" << endl;  
    }  
    cout << "All done." << endl;  
    return 0;  
}
```

Output:

```
DoSomething called.  
DoSomething failed : 'something is wrong.'  
All done.
```

Exception Handling in C++

```
bool DoSomething(string* error_message) {
    cout << "DoSomething called." << endl;
    // Do something...
    if (something_is_wrong) {
        *error_message = "something is wrong.";
        return false;
    }
    // Do the rest...
    cout << "DoSomething finished." << endl;
    return true;
}
```

```
bool DoSomethingMore(string* error_message) {
    cout << "DoSomethingMore called." << endl;
    if (!DoSomething(error_message)) {
        return false;
    }
    // Do something more...
    if (something_is_wrong) {
        *error_message = "something is wrong.";
        return false;
    }
    // Do the rest...
    cout << "DoSomethingMore finished." << endl;
    return true;
}
```

```
int main() {
    string error_message;
    if (!DoSomethingMore(&error_message)) {
        cout << "DoSomethingMore failed : '"
            << error_message << "'" << endl;
    }
    cout << "All done." << endl;
    return 0;
}
```

Output:

```
DoSomethingMore called.
DoSomething called.
DoSomethingMore failed : 'something is wrong.'
All done.
```

try - throw - catch

- **try** : be prepared to catch certain exceptions specified in the following catch blocks thrown within the block.
- **catch** : catches the exception of the given type, then handles it - either re-throws it or stops propagating it.
- **throw** : invokes (throws) an exception event. It will be caught and handled by the try-catch block.
(it also is used to specify which exceptions can be thrown in a function.)
- Any object can be thrown as an exception. The thrown object is copied.

Toy Example with Exception Handling

```
9      try
10     {
11         cout << "Enter number of donuts:\n";
12         cin >> donuts;
13         cout << "Enter number of glasses of milk:\n";
14         cin >> milk;
15
16         if (milk <= 0)
17             throw donuts;
18
19         dpg = donuts/static_cast<double>(milk);
20         cout << donuts << " donuts.\n"
21              << milk << " glasses of milk.\n"
22              << "You have " << dpg
23              << " donuts for each glass of milk.\n";
24     }
25     catch(int e)
26     {
27         cout << e << " donuts, and No Milk!\n"
28              << "Go buy some milk.\n";
29     }
```

- Code between keywords *try* and *catch*
 - Same code from ordinary version, except

```
if statement simpler:  
if (milk <= 0)  
    throw donuts;
```

- Much cleaner code
 - If "no milk" → do something exceptional
- The "something exceptional" is provided after keyword *catch*

- Try block
 - Handles "normal" situation
- Catch block
 - Handles "exceptional" situations
- Provides separation of normal from exceptional
 - Not big deal for this simple example, but important concept

- Basic method of exception-handling is try-throw-catch
- Try block:

```
try  
{  
    Some_Code;  
}
```

- Contains code for basic algorithm when all goes smoothly

- Inside try-block, when something unusual happens:

```
try
{
    Code_To_Try
    if (exceptional_happened)
        throw donuts;
    More_Code
}
```

- Keyword *throw* followed by exception type
- Called "throwing an exception"

- When something thrown → goes somewhere
 - In C++, flow of control goes from try-block to catch-block
 - try-block is "exited" and control passes to catch-block
 - Executing catch block called "catching the exception"
- Exceptions must be "handled" in some catch block

- Recall:

```
catch(int e)
{
    cout << e << " donuts, and no milk!\n";
    << " Go buy some milk.\n";
}
```

- Looks like function definition with int parameter!
 - Not a function, but works similarly
 - Throw like "function call"

- Recall: `catch(int e)`
- "e" called catch-block parameter
 - Each catch block can have at most ONE catch-block parameter
- Does two things:
 1. type name specifies what kind of thrown value the catch-block can catch
 2. Provides name for thrown value caught; can "do things" with value

```
void ThrowsException() {  
    throw string("Exception!");  
}  
  
void DoSomething() {  
    cout << "DoSomething called." << endl;  
    // Do something...  
    if (something_is_wrong) ThrowsException();  
    cout << "DoSomething finished." << endl;  
}
```

```
int main() {  
    try {  
        DoSomething();  
    } catch (string s) {  
        cout << "Caught an exception '"  
            << s << "'" << endl;  
    }  
    cout << "All done." << endl;  
    return 0;  
}
```

Output:

```
DoSomething called.  
Caught an exception 'Exception!'  
All done.
```

- Exceptions can be propagated through several levels of function calls if there is no try-catch block for the exception type.

```
void ThrowsException() {  
    throw string("Exception!");  
}  
  
void DoSomething() {  
    cout << "DoSomething called." << endl;  
    // Do something...  
    if (something_is_wrong) ThrowsException();  
    cout << "DoSomething finished." << endl;  
}  
  
void DoSomethingMore() {  
    cout << "DoSomethingMore called." << endl;  
    DoSomething();  
    // Do something more...  
    if (something_is_wrong) {  
        throw string("error.");  
    }  
    cout << "DoSomethingMore finished." << endl;  
}
```

```
int main() {  
    try {  
        DoSomethingMore();  
    } catch (string s) {  
        cout << "Caught an exception '"  
            << s << "'" << endl;  
    }  
    cout << "All done." << endl;  
    return 0;  
}
```

Output:

```
DoSomethingMore called.  
DoSomething called.  
Caught an exception 'Exception!'  
All done.
```

- throw statement can throw value of any type
- Exception class
 - Contains objects with information to be thrown
 - Can have different types identifying each possible exceptional situation
 - Still just a class
 - An "exception class" due to how it's used

- Consider:

```
class NoMilk
{
    public:
        NoMilk() { }
        NoMilk(int howMany) : count(howMany) { }
        int getcount() const { return count; }
    private:
        int count;
};
```

- throw NoMilk(donuts);
 - Invokes constructor of NoMilk class

- try-block typically throws any number of exception values, of differing types
- Of course only one exception thrown
 - Since throw statement ends try-block
- But different types can be thrown
 - Each catch block only catches "one type"
 - Typical to place many catch-blocks after each try-block
 - To catch "all-possible" exceptions to be thrown

- Order of catch blocks important
- Catch-blocks tried "in order" after try-block
 - First match handles it!
- Consider:
catch (...) { }
- Called "catch-all", "default" exception handler
- Catches any exception
- Ensure catch-all placed AFTER more specific exceptions!
 - Or others will never be caught!

- Consider:

```
class DivideByZero  
{ }
```

- No member variables
- No member functions (except default constructor)
- Nothing but it's name, which is enough
 - Might be "nothing to do" with exception value
 - Used simply to "get to" catch block
 - Can omit catch block parameter

- Function might throw exception
- Callers might have different "reactions"
 - Some might desire to "end program"
 - Some might continue, or do something else
- Makes sense to "catch" exception in calling function's try-catch-block
 - Place call inside try-block
 - Handle in catch-block after try-block

- Consider:

```
try
{
    quotient = safeDivide(num, den);
}
catch (DivideByZero)
{ ... }
```

- safeDivide() function throws DividebyZero exception
 - Handled back in caller's catch-block

- Functions that don't catch exceptions
 - Should "warn" users that it could throw
 - But it won't catch!
- Should list such exceptions:

```
double safeDivide(int top, int bottom) throw (DividebyZero);
```

- Called "exception specification" or "throw list"
- Should be in declaration and definition
- All types listed handled "normally"
- If no throw list → all types considered there

- If exception thrown in function NOT in throw list:
 - No errors (compile or run-time)
 - Function unexpected() automatically called
 - Default behavior is to terminate
 - Can modify behavior
- Same result if no catch-block found

- Exceptions can be propagated through several levels of function calls if there is no try-catch block for the exception type.

```
void ThrowsException() {  
    throw string("Exception!");  
}  
  
void DoSomething() {  
    cout << "DoSomething called." << endl;  
    // Do something...  
    if (something_is_wrong) ThrowsException();  
    cout << "DoSomething finished." << endl;  
}  
  
void DoSomethingMore() {  
    cout << "DoSomethingMore called." << endl;  
    DoSomething();  
    // Do something more...  
    if (something_is_wrong) {  
        throw string("error.");  
    }  
    cout << "DoSomethingMore finished." << endl;  
}
```

```
int main() {  
    try {  
        DoSomethingMore();  
    } catch (string s) {  
        cout << "Caught an exception '"  
            << s << "'" << endl;  
    }  
    cout << "All done." << endl;  
    return 0;  
}
```

Output:

```
DoSomethingMore called.  
DoSomething called.  
Caught an exception 'Exception!'  
All done.
```

- Uncaught exceptions cause the program to halt (thus dangerous).

```
void ThrowsException() {  
    throw string("Exception!");  
}  
  
void CallsOne() {  
    ThrowsException();  
}  
  
void CallsTwo() {  
    try {  
        CallsOne();  
    } catch (MyException e) {  
        cout << "Caught a MyException '"  
            << e.msg << "'" << endl;  
    }  
}
```

```
int main() {  
    try {  
        CallsTwo();  
    } catch (MyException e) {  
        cout << "Caught an exception '"  
            << e.msg << "'" << endl;  
    }  
    return 0;  
}
```

Output (depending on systems):
terminate called throwing an exception
Abort trap: 6

- `throw (. . .)` after a (member) function declaration specifies which exceptions it may generate - but not strictly enforced.

```
void ThrowsException() throw (string) {  
    throw string("Exception!");  
}  
  
void CallsTwo() throw (string, MyException)  
{  
    ThrowsException();  
    throw MyException("test");  
}  
  
void CallsOther() throw () {  
    // ...  
}
```

```
int main() {  
    try {  
        CallsTwo();  
    } catch (MyException e) {  
        cout << "Caught an exception '"  
            << e.msg << "'" << endl;  
    }  
    return 0;  
}
```

Output (depending on systems):
terminate called throwing an exceptionAbort
trap: 6

- Class hierarchy is sometimes useful in defining and catching exceptions - use references.

```
struct MyException : public std::exception {  
    int my_counter;  
};  
  
struct MySpecializedException  
    : public MyException {  
    int special_counter;  
};
```

```
int main() {  
    try {  
        // This may throw  
        // MySpecializedException.  
        CallSpecializedFunction();  
        // This may throw MyException.  
        CallGeneralFunction();  
    } catch (MySpecializedException& e) {  
        // ...  
    } catch (MyException& e) {  
        // ...  
    } catch (std::exception& e) {  
        // ...  
    }  
    return 0;  
}
```

Exception Handling in C++

```
#include <exception>    // std::exception

class exception {
public:
    exception () noexcept;
    exception (const exception&) noexcept;
    exception& operator= (const exception&) noexcept;
    virtual ~exception();
    virtual const char* what() const noexcept;
}

struct MyException : std::exception {
    string msg;

    MyException(const string& m) : msg(m) {}
};

void DoSomething() {
    cout << "DoSomething called." << endl;
    throw MyException("DoSomething");
}
```

```
void DoSomethingElse() {
    cout << "DoSomethingElse called." << endl;
    throw new MyException("DoSomethingElse");
}

int main() {
    try {
        DoSomething();
    } catch (std::exception e) {
        cout << "Caught an exception" << endl;
    }
    try {
        DoSomethingElse();
    } catch (MyException* e) {
        cout << "Caught a MyException "
            << e->msg << endl;
        delete e;
    }
    return 0;
}
```

Output:

```
DoSomething called.
Caught a MyException DoSomething
DoSomethingElse called.
Caught a MyException DoSomethingElse
```

- `void someFunction()`
 `throw(DividebyZero, OtherException);`
 //Exception types DividebyZero or OtherException
 //treated normally. All others invoke unexpected()
- `void someFunction() throw ();`
 //Empty exception list, all exceptions invoke unexpected()
- `void someFunction();`
 //All exceptions of all types treated normally

- Remember: derived class objects also objects of base class
- Consider:
 - D is derived class of B
- If B is in exception specification →
 - Class D thrown objects will also be treated normally, since it's also object of class B
- Note: does not do automatic type cast:
 - double will not account for throwing an int

- Default action: terminates program
 - No special includes or using directives
- Normally no need to redefine
- But you can:
 - Use `set_unexpected`
 - Consult compiler manual or advanced text for details

- Typical to separate throws and catches
 - In separate functions
- Throwing function:
 - Include throw statements in definition
 - List exceptions in throw list
 - In both declaration and definition
- Catching function:
 - Different function, perhaps even in different file

```
void functionA() throw (MyException)
{
    ...
    throw MyException(arg);
    ...
}
```

- Function throws exception as needed

- Then some other function:

```
void functionB()
{
    ...
    try
    {
        ...
        functionA();
        ...
    }
    catch (MyException e)
    { // Handle exception
    }
    ...
}
```

- Should catch every exception thrown
- If not → program terminates
 - terminate() is called
- Recall for functions
 - If exception not in throw list: unexpected() is called
 - It in turn calls terminate()
- So same result

- Exceptions alter flow of control
 - Similar to old "goto" construct
 - "Unrestricted" flow of control
- Should be used sparingly
- Good rule:
 - If desire a "throw": consider how to write program without throw
 - If alternative reasonable → do it

- Useful to have; consider:
 - DivideByZero class derives from:ArithmeticError exception class
 - All catch-blocks for ArithmeticError also catch DivideByZero
 - If ArithmeticError in throw list, then DividebyZero also considered there

- new operator throws bad_alloc exception if insufficient memory:

```
try
{
    NodePtr pointer = new Node;
}
catch (bad_alloc)
{
    cout << "Ran out of memory!";
    // Can do other things here as well...
}
```

- In library <new>, std namespace

- Legal to throw exception IN catch-block!
 - Typically only in rare cases
- Throws to catch-block "farther up chain"
- Can re-throw same or new exception
 - rethrow;
 - Throws same exception again
 - throw newExceptionUp;
 - Throws new exception to next catch-block

Thank you!
